# Chapter 1

## Introduction

Village n°1 is a belgian company employing persons with disabilities. They offer services to companies and private individuals such as industrial jobs. They are currently in the process of automating the way they schedule these jobs. The aim of this thesis is to solve their resource allocation problem automatically. First, we will introduce two models to solve this problem: a Mixed Integer Programming and a Constraint Programming model. We will then analyze and compare the performance of both models.

TODO

TODO

TODO

TODO

This thesis is organized as follows

Chapter 2 introduces the resource allocation problem of Village n°1.

Chapter 3 describes the state-of-the-art in the domains of Mixed Integer Programming and Constraint Programming.

Chapter 4 gives a formal definition of both MIP and CP models.

Chapter 5 describes the implementation of the models.

Chapter 6 presents the carried experiments and performance results of both models.

Chapter 7 TODO

# Chapter 2

## The Village n°1 problem

This chapter presents the resource allocation problem. We first introduce the general problem and its constraints, the formal models are described in Chapter 4.

The Village n°1 problem consists of allocating resources to work demands. This problem is a type of staff scheduling problem, it can be seen as a variant of the well known *Nurses Scheduling Problem* (NSP) [1]. The goal of the NSP is to assign nurses to shifts such that the entire schedule is satisfied. This type of problem often have hard constraints to state restrictions and soft constraints to state preferences.

Village n°1 has internal work for their employees but also receives external labor requests. The problem is separated in multiple time periods all equal in time. A demand often occurs in multiple time slots and consists of a required number of workers, an eventual work location and additional resources like machines or vehicles. Each demand has:

- A given set of time periods.
- A required number of workers per period.
- Some skills requirements to be fulfilled by the workers. It imposes that some workers have the needed capacities to work at a given position (e.g. package lifter).
- A list of machines to perform the work.
- An eventual list of possible locations where the demand can be executed and a vehicle to drive the workers to destination. A demand can only have a location if it is an external labor request. Internal work to the company use predefined locations.
- An eventual need for a worker supervisor which will supervise the group.

Each worker has:

- Some skills and restrictions (e.g. package lifter, supervisor, etc.)
- A list of availabilities at which the worker can work.
- A list of incompatibilities with other workers (i.e. workers that can't work together).
- A list of incompatibilities with clients (i.e. workers that can't work for clients).

The goal is to assign workers, machines and locations to a list of demands over the set of all time slots. Each resource can only be assigned once per time period and need to satisfy all the constraints stated by the demand. The sub-goal is to also assign workers in such a way that they work for the longest time possible at the same position and such that the assignments between workers are balanced throughout the entire schedule.

## 2.1 Constraints

### 2.1.1 Hard Constraints

#### **Respect worker availabilities**

A worker has a set of availabilities and should not be assigned to a shift when not available.

#### **Respect demand occurrences**

A demand has a set of time periods in which it occurs, no workers should be assigned to that demand if the demand is not occurring.

#### **No worker should be assigned twice for the same period**

A worker obviously can't work at two positions at the same time.

#### **Required number of workers**

A demand has a needed number of workers to be satisfied. For each time period a demand is occurring, it should have the required number of workers assigned to it.

### **Skill restrictions**

Each position of a demand might require skills to be satisfied. To be assigned to that position, a worker must have the required skills.

### **Worker-worker incompatibilities**

Workers might be incompatible with each other. Such workers can't be assigned together at the same time period.

### **Worker-client incompatibilities**

A worker and a client might be incompatible with each other. If this is the case, the worker must not be assigned at a demand for such client.

### **The required machines must always be assigned**

A demand has machine needs. Such machines should always be assigned for a demand to be satisfied.

### **No machines should be assigned twice for the same period**

A machine is assigned for the entirety of a demand. It can be used for other demands that do not overlap in time with the first one. But it can never be assigned twice for the same time period.

### **The location assigned must be in the set of possible locations**

A demand has a set of possible locations. Only one of those locations can be assigned to that demand.

### **No location should be assigned twice for the same period**

As with machines, locations must be assigned only once per time period.

## **2.1.2 Soft Constraints**

### **Client-worker preference**

A client might prefer some workers over others. We use a soft constraint for this as it might not always be possible to satisfy.

### **Contiguous shifts**

A demand consists of multiple positions over a period of time. For each position, a worker should keep working at that position for the longest time possible. We want to avoid the hassle of changing shift everytime. As this constraint is harder to solve, we express it as a soft constraint and minimize the number of violations.

### **Working requirements**

Workers can have minimum and maximum working periods. We want to make sure that these requirements are respected as much as possible.

# Chapter 3

## State of the art

### 3.1 Mixed Integer Programming

The most common *Mixed Integer Programming* (MIP) problems are of the form:

$$\min \quad \mathbf{c}^T \mathbf{x} \tag{3.1}$$

$$\text{s.t.} \quad A\mathbf{x} = \mathbf{b} \tag{3.2}$$

$$\mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \tag{3.3}$$

$$\text{Some or all } x_i \text{ must take integer values} \tag{3.4}$$

(3.1) is the problem objective.  $\mathbf{c}^T$  is the vector of coefficient,  $\mathbf{x}$  is the vector of variables. (3.2) are the linear constraints.  $\mathbf{b}$  is a vector of bounds while  $A$  is a matrix of coefficients for the constraints. (3.3) are the bound constraints. Each  $x_i$  can only take values between  $l_i$  and  $u_i$ . And finally, (3.4) states the integrality constraints over some or all variables.

MIP problems are usually solved using a branch-and-bound algorithm [2]. The process is as follow: we start with the MIP formulation and remove all integrality constraints to create a resulting linear-programming (LP) relaxation to the original problem. The relaxation can be solved easily compared to the original problem. The result might satisfy all integrality constraints and be a solution to the original problem. But more often than not, a variable has a fractional value. We can then solve two relaxations by imposing two additional constraints. For example, if  $x$  takes value 5.5, we add the following linear constraints:  $x \leq 5.0$  and  $x \geq 6.0$ . This process is repeated throughout the search tree (Figure 3.1) a valid solution is found. More techniques are used to find solution more efficiently. Each solver uses its own algorithm (e.g Gurobi Optimizer [2]).

A binary tree diagram illustrating a search process. The root node is white. It has a left child (white) and a right child (white). The left child has a left child (white) and a right child (green). The right child of the left child is highlighted in purple. Arrows indicate the path from the root to the highlighted node.

Figure 3.1: MIP Branch & Bound search tree [2]

The *Gurobi Optimizer* [3] is a state-of-the-art commercial solver for mathematical programming. Gurobi includes multiple solvers, among those: (i) Linear Programming (LP); (ii) Mixed Integer Linear Programming (MILP), abbreviated as MIP.

## 3.2 Constraint Programming

### 3.2.1 Global Constraints

[...] a constraint  $C$  is often called “global” when “processing”  $C$

as a whole gives better results than “processing” any conjunction of constraints that is “semantically equivalent” to  $C$ .

The author also define three types of constraint globality, we are mostly interested in what he refers to *operational globality*. Those constraints can be decomposed into multiple simpler constraints but the filtering quality of the decomposition is often worse than its global counterpart.

There also exists soft variants of global constraints where those constraints are associated with a number of violations which is usually minimized afterwards. This is particularly useful for problems with impossible solution while using the hard constraints version.

### **alldifferent constraint**

The **alldifferent** constraint [6] is one of the most famous global constraint used in Constraint Programming. This constraint is defined over a subset of variables for which values must be different. More formally:

$$\text{alldifferent}(x_1, \dots, x_n) = \{(d_1, \dots, d_n) \mid d_i \in D(x_i), d_i \neq d_j \forall i \neq j\}$$

This constraint can be decomposed into multiple binary inequalities. It makes **alldifferent** an operational global constraint. It can be proven that the filtering of the global constraint cannot be achieved with a decomposition. As an example, let's define three variables  $x_1$ ,  $x_2$  and  $x_3$  respectively taking domains  $\{1, 2\}$ ,  $\{1, 2\}$ ,  $\{1, 2, 3, 4\}$ . The global constraint would be able to successfully filter 1 and 2 from the domain of  $x_3$  because the values are always taken by  $x_1$  and  $x_2$ . However, the decomposition is not able to filter those values.

### **Global Cardinality Constraint**

The global cardinality constraint (**gcc**) [7] is a generalization of the **alldifferent** constraint. It does not enforces (although it can) the uniqueness of values of its variables but instead enforces that the cardinality of each value  $d_i$  for all its variables in its scope lies between a lowerbound and an upperbound, respectively  $l_i$  and  $u_i$ .

$$\text{gcc}(X, l, u) = \{(d_1, \dots, d_n) \mid d_i \in D(x_i), l_d \leq |\{d_i \mid d_i = d\}| \leq u_d, \forall d \in D(X)\}$$

As stated above, we can express the **alldifferent** constraint with this definition:

$$\text{gcc}(\{x_1, \dots, x_n\}, [1, \dots, 1], [1, \dots, 1])$$

We are also interested in a soft variant of `gcc` called `softgcc` [8]. The violation associated with this constraint is the sum of excess or shortage [9] for each value.

$$\begin{aligned} \text{softgcc}(X, l, u, Z) &= \{(d_1, \dots, d_n) \mid d_i \in D(x_i), d_z \in D(Z), \text{viol}(d_1, \dots, d_n) \leq d_z\} \\ \text{with } \text{viol}(d_1, \dots, d_n) &= \sum_{d \in D(X)} \max(0, |\{d_i \mid d_i = d\}| - u_d, l_d - |\{d_i \mid d_i = d\}|) \end{aligned}$$

### 3.2.2 OscaR

*OscaR* [10] is a Scala toolkit for solving Operations Research problems. *OscaR* has multiple optimization techniques available: (i) Constraint Programming; (ii) Constraint Based Local Search (CBLS); (iii) Derivative Free Optimization; (iv) Visualization.

The project is mainly developped by UCLouvain and the research group of Pierre Schaus. But some companies like *N-Side* and *CETIC* allocate resources to improve it.

The library of *OscaR* in which this project is interested in is the Constraint Programming library. It offers a lot of existing constraints and abstractions. Some black-box searches are also implemented but we can bring our own heuristics to drive the search forward.

# Chapter 4

## Models for the Village n°1 problem

In this chapter, we present models for both Mixed Integer Programming and Constraint Programming. We first start by presenting constraints that need to be respected. We then present formal notations used by both models. The mathematical (MIP) model is presented first for reference followed by the CP model which is an adaptation of the mathematical model.

### 4.1 Notations

- Set of periods:

$$T = \{0, \dots, n \mid n \in \mathbb{N}\}$$

- Set of workers:

$$W = \{w_0, \dots, w_n \mid n \in \mathbb{N}\}$$

- $w^T \subseteq T$ : Availabilities of a worker:

- Set of machines:

$$M = \{m_0, \dots, m_n \mid n \in \mathbb{N}, m_n \in \mathbb{N}\}$$

Let's also define the set of machines for a given machine value (i.e name).  $M_i$  is the set of machines that takes the value  $i$ .

$$M_i = \{m_j \mid m_j = i, \forall j \in M\}$$

- Set of vehicles:

$$V = \{v_0, \dots, v_n \mid n \in \mathbb{N}\}$$

This could also be expressed as a subset of machines:

$$V \subseteq M$$

- Set of zones:

$$Z = \{z_0, \dots, z_n \mid n \in \mathbb{N}\}$$

- Set of demands:

$$D = \{d_0, \dots, d_n \mid n \in \mathbb{N}\}$$

- $d^w \in \mathbb{N}$ : Required number of workers for this demand
- $d^T \subseteq T$ : Possible periods for a demand
- $d^Z \subseteq Z$ : Possible zones for a demand
- $d^M \subseteq M$ : List of required machines by the demand
- $d^c \in C$ : Client for that demand
- $d^S \in S$ : List of skill required by the demand (each skill need to have a different worker)
- $d^{s_0}$ : The first skill in  $d^S$
- $d^{S^+}$ : Set of additional skills that can be satisfied by any worker in that demand
- $d^{s_0^+}$ : The first skill in  $d^{S^+}$
- $d^P \in \{0, \dots, d^w - 1\}$ : List of positions
- $d^O \subseteq D$ : Set of overlapping demands in time for that demand. e.g. the overlapping demands for demand 1 is  $d_1^O$

Let's also define the set of demands where the client  $c$ :  $D_c = \{d \mid d^c = c\}$

- Set of clients:

$$C = \{c_0, \dots, c_n \mid n \in \mathbb{N}\}$$

- Set of skills:

$$S = \{s_0, \dots, s_n \mid n \in \mathbb{N}\}$$

Let's also define the set of workers that satisfy a skill or skill set:

$$W_s \subseteq W, s \in S$$

- Set of working requirements:

$$R = \{r_0, \dots, r_n \mid n \in \mathbb{N}\}$$

- $r_w$ : The worker concerned with this requirement
- $r_{min}$ : The minimum number of periods the worker has to work
- $r_{max}$ : The maximum number of periods the worker has to work
- Set of incompatibilities between workers:

$$I_{ww} = \{(i, j) \in \mathbb{N} \times \mathbb{N} \mid w_i, w_j \in W, w_i \neq w_j\}$$

- Set of incompatibilities between workers and clients:

$$I_{wc} = \{(i, j) \in \mathbb{N} \times \mathbb{N} \mid w_i \in W, c_j \in C\}$$

## 4.2 Mixed Integer Programming Model

We first start by presenting the mathematical model, we describe the variables needed to model our problem and the constraints associated to them.

### 4.2.1 Variables

To represent our problem in MIP, we will need three types of variables, one per resource.

$$\begin{aligned} w_{ijkl} &= \begin{cases} 1 & \text{if worker } i \text{ is working at time } j \text{ for demand } k \text{ at position } l \\ 0 & \text{otherwise} \end{cases} \\ s_{jkl} &= \begin{cases} 1 & \text{if no worker is assigned at time } j \text{ for demand } k \text{ at position } l \\ 0 & \text{otherwise} \end{cases} \\ m_{ij} &= \begin{cases} 1 & \text{if machine } i \text{ is used for demand } j \\ 0 & \text{otherwise} \end{cases} \\ z_{ij} &= \begin{cases} 1 & \text{if zone } i \text{ is used for demand } j \\ 0 & \text{otherwise} \end{cases} \end{aligned}$$

This is in fact a binary Integer Programming model as every variables is a  $\{0, 1\}$  integer.

As solution can be partial, we need to introduce a way to allow the absence of worker for a given position. In MIP, we model this by having the variables  $s_{jkl}$ ,  $s$  for *sentinel*. This variable is one, if and only if all the corresponding worker variables ( $w_{ijkl}, \forall_i$ ) are equal to zero. The goal will be to minimize the number of sentinel variables assigned to one.

### 4.2.2 Complete Model

$$\min \sum_{k \in D} \sum_{l \in d_k^P} \sum_{i \in W} \min(\sum_{j \in T} w_{ijkl}, 1) \quad (4.1a)$$

$$+ \sum_{j \in T} \sum_{k \in D} \sum_{l \in d_k^P} s_{jkl} \quad (4.1b)$$

$$+ \sum_{r \in R} \left( \max(r_{\min} - \text{occ}_{r_w}, 0) + \max(r_{\max} - \text{occ}_{r_w}, 0) \right) \quad (4.1c)$$

$$\text{s.t.} \quad \sum_{i \in W} w_{ijkl} + s_{jkl} = 1, \quad \forall k \in D, j \in d_k^T, l \in d_k^P \quad (4.2)$$

$$\sum_{k \in D} \sum_{l \in d_k^P} w_{ijkl} \leq 1, \quad \forall i \in W, j \in T \quad (4.3)$$

$$t_j \notin d_k^T \implies \forall i, l \ w_{ijkl} = 0, \quad \forall j \in T, k \in D \quad (4.4)$$

$$t_j \notin w_i^T \implies \forall k, l \ w_{ijkl} = 0, \quad \forall j \in T, i \in W \quad (4.5)$$

$$t_j \notin d_k^T \implies \forall l \ s_{jkl} = 0, \quad \forall j \in T, k \in D \quad (4.6)$$

$$t_j \notin w_i^T \implies \forall l \ s_{jkl} = 0, \quad \forall j \in T, i \in W \quad (4.7)$$

$$\sum_{l \in d_k^P} w_{ajkl} + w_{bjkl} < 2, \quad \forall (a, b) \in I_{ww}, j \in T, k \in D \quad (4.8)$$

$$d_k^c = c \implies \forall l \ w_{ijkl} = 0, \quad \forall (i, c) \in I_{wc}, j \in T, k \in D \quad (4.9)$$

$$w_{ijkl} = 0, \quad \forall j \in T, k \in D, l \in d_k^P, \\ i \in W \setminus W_{d_k^{sl}} \quad (4.10)$$

$$\sum_{l \in d_k^P} w_{ijkl} \geq 1, \quad \forall j \in T, k \in D, s \in d_k^{S+}, i \in W_{d_k^{S+}} \quad (4.11)$$

$$z_i \notin d_j^Z \implies z_{ij} = 0, \quad \forall i \in Z, j \in D \quad (4.12)$$

$$|d_j^Z| > 0 \implies \sum_{i \in Z} z_{ij} = 1, \quad \forall j \in D \quad (4.13)$$

$$z_{ij} + z_{ik} \leq 1, \quad \forall j \in D, k \in d_j^O, i \in Z \quad (4.14)$$

$$m_i \notin d_j^M \implies m_{ij} = 0, \quad \forall i \in M, j \in D \quad (4.15)$$

$$\sum_{i \in M_k} m_{ij} = |d_j^{M_k}|, \quad j \in D, k \in d_j^M \quad (4.16)$$

$$m_{ij} + m_{ik} \leq 1, \quad \forall j \in D, k \in d_j^O, i \in M \quad (4.17)$$

$$w_{ijkl} \in \{0, 1\}, \quad \forall i \in W, j \in T, k \in D, l \in d_k^P \quad (4.18)$$

$$s_{jkl} \in \{0, 1\}, \quad \forall j \in T, k \in D, l \in d_k^P \quad (4.19)$$

$$m_{ij} \in \{0, 1\}, \quad \forall i \in M, j \in D \quad (4.20)$$

$$z_{ij} \in \{0, 1\}, \quad \forall i \in Z, j \in D \quad (4.21)$$

$$occ_i = \sum_{j \in T} \sum_{k \in D} \sum_{l \in d_j^P} w_{ijkl}, \quad \forall i \in W \quad (4.22)$$

The objective function is stated in (4.1), it is split in multiple parts, it minimizes (i) the number of different workers for every position between periods of that demand (4.1a),  $\min(\sum_{j \in T} w_{ijkl}, 1)$  is one if the worker  $i$  is working for that position at that time, 0 otherwise. Hence, the sum of that value for all worker will be equal to the number of worker for that shift; (ii) the number of *sentinel* worker assigned to demands (4.1b); (iii) the number of violations of working requirements (4.1c).

Constraint (4.2) ensures that each position is filled by only one worker. The sentinel worker being a valid assignment is also part of the sum.

Constraint (4.3) ensures that no worker works for multiple demands at the same time period.

The constraints (4.4) and (4.5) ensures that no worker is working for a demand thais not occurring or when is himself not available.

The constraints (4.6) and (4.7) fullfil the same role as (4.4) and (4.5) but for sentinel variables.

Constraint (4.8) ensures that no incompatible workers work together while (4.9) ensures that no incompatible pair of worker and client work together.

Constraint (4.10) ensures that no worker work for a position in which they are not qualified to work at. Constraint (4.11) ensures that for each additional skills, at least one worker in the group has that skill.

Constraint (4.12) ensures that no zone is assigned to a demand in which this zone is not a possible assignment. (4.13) ensures that only one zone is assigned to this demand if this demand is in need of a zone. Constraint (4.14) ensures that no zone is assigned to two overlapping demands in time.

Constraint (4.15) ensures that no machine is assigned to a demand not in need of that machine. Constraint (4.16) ensures that the required number for each machine is satisfied. And again, (4.17) ensures that no machine is assigned to two overlapping demands in time.

Finally (4.18), (4.19), (4.20) and (4.21) ensure the variables only takes binary values.

### 4.3 Constraint Programming Model

The translation to the mathematical (MIP) model to the CP model is fairly straightforward. Binary variables are translated to integer variables, each value representing one resource (i.e. worker, zone or machines). For example, binary variables  $w_{0jkl}, \dots, w_{njkl}$  are transformed to a single variable  $w_{jkl} \in \{0, \dots, n\}$

### 4.3.1 Variables

First, we need to express the set of workers for each demand at each time period in which that demand occurs.

$$w_{ijk} \in W \quad (4.23)$$

(4.23) is the worker working at time  $i$  for demand  $j$  at the  $k^{\text{th}}$  position with  $t_i \in T$ ,  $d_i \in D$ ,  $t_i \in d_j^T$  and  $k \in d_j^P$ . This is done by using a 3-dimensional array of variables. The first dimension being the indices of the time periods, the second dimension is the indices of the demands while the last dimension is the list of worker variables. This last dimension has the size of the number of required workers for that demand.

The same reasoning is used for zones and machines:

$$m_{ij} \in M \quad (4.24)$$

$$z_i \in Z \quad (4.25)$$

(4.24) is the  $j^{\text{th}}$  machine used for demand  $i$  while (4.25) is the zone used for demand  $i$

Some constraints are already satisfied by the modeling of the variables, like the number of required resources (i.e. worker, location, machine) per demand.

As explained in the problem description and in the mathematical model section. We need to allow partial solutions where we have a fictitious worker that can work at any time. We will add this value to every worker variable domain but ignore it during the constraint propagation. We define this worker by  $\sigma \notin W$ . The actual value of this worker does not matter as long as it's not a value in  $W$  but for simplicity, we will define  $\sigma = -1$ .

### 4.3.2 Complete Model

For this model, we define additional notations:

- $N_{jk}$  denotes the number of different workers for shift  $k$  of demand  $j$ , these are variables added separate to the decision variables.
- $W_{jk} = \{w_{ijk} \mid i \in d_j^T\}$  denotes the set of worker variables for demand  $j$  at position  $k$  accross all time periods of that demand.
- $X_i = \{w_{ijk} \mid j \in D, k \in d_j^P\}$  denotes the set of worker variables for all the demands accross time period  $t_i$

- $Z_i^O = \{z_j \mid j \in d_i^O\}$  denotes the set of zone variables for demands that overlap in time with  $d_i$
- $M_i^O = \{m_{jk} \mid j \in d_i^O, k \in \{0, \dots, |d_j^M| - 1\}\}$  denotes the set of machine variables for demands that overlap in time with  $d_i$
- $P_{ij}$  denotes the set of permutations of pairs of worker variables for a demand  $j$  at time  $i$ .

$$\min \sum_{j \in D} \sum_{k \in D_j^P} N_{jk} \quad (4.26)$$

$$\text{s.t. } \text{atLeastNValue}(W_{jk}, N_{jk}), \quad \forall j \in D, k \in d_j^P \quad (4.27)$$

$$\text{allDifferentExcept}(X_i, \{\sigma\}), \quad \forall i \in T \quad (4.28)$$

$$\text{softGcc}(X, \sigma \rightarrow \sigma, 0, 0, v_\sigma) \quad (4.29)$$

$$\text{softGcc}(X, 0 \rightarrow |W| - 1, r_{\min}, r_{\max}, v_r) \quad \forall \quad (4.30)$$

$$\text{allDifferent}(Z_i^O), \quad \forall i \in D \quad (4.31)$$

$$\text{allDifferent}(M_i^O), \quad \forall i \in D \quad (4.32)$$

$$\text{notEqual}(w_{ijk}, w), \quad \forall (w, c) \in I_{wc}, \quad (4.33)$$

$$i \in T, j \in D_c, k \in d_j^P$$

$$\text{negativeTable}(a, b, I_{ww}), \quad \forall (a, b) \in P_{ij} \quad (4.34)$$

$$w_{ijk} \in W_{d_j^{sk}} \cap \{w \mid t_i \in w^T\} \cap \{\sigma\}, \quad \forall j \in D, i \in d_j^T, k \in d_j^P \quad (4.35)$$

$$z_i \in d_i^Z, \quad \forall i \in D \quad (4.36)$$

$$m_{ij} \in \{m \mid m \in W \wedge m = d_i^{M_j}\}, \quad \forall i \in D, j \in d_i^M \quad (4.37)$$

This model is simpler than the mathematical one described Section 4.2. It needs less constraints to express the same problem. For example, (4.35) expresses multiple constraints (i.e. workers are restricted to positions with respect to their skills and to their availabilities) in only one step which is the initialization of the variable. Hence, no constraints will run during the solving process. (4.35) also states that we add a fictitious worker  $\sigma \notin W$  to every worker variables.

(4.36) expresses that the domain of zone variables are limited to the possible zones of a demand and (4.37) states that the domain of each machine variables for a demand are limited to the possible machines for that need.

(4.28) states that no workers should work for two positions at the same time. Constraint (4.33) states the incompatibilities between clients and workers and restricts workers to work for incompatible clients while (4.34) prevent incompatible workers to work together.

Constraint (4.31) and (4.32) state that no zones and machines should be used for two overlapping demands.

Finally, for the objective, constraint (4.27) states that  $N_{jk}$  will be equal to the number of different workers for the same position throughout time periods. The objective itself (4.26) is the minimization of the sum of all  $N_{jk}$ , hence minimizing the number of change between shifts.

### 4.3.3 Search

We define a heuristic that allows: (i) the fictitious worker to never be selected if there is another value available in the domain of the variable; (ii) the worker chosen for a variable is the most available for that demand but is also the less available for other demands.

#### Variable Heuristic

The variable heuristic used for the search is a first-fail heuristic. In other words, the heuristic will chose the variable will the smallest domain. This allows variable with only one value alongside the fictitious value  $\sigma$  to always be selected first.

#### Value Heuristic

We define a value heuristic that we call the *most available heuristic*. This heuristic consists of two value ordering.

1. The first ordering orders the workers from most available to least available throughout the duration of the demand. This allows the search to select workers that are more likely to work for that demand throughout all periods.
2. If workers have the same availabilities for a demand, they are ordering in respect to their remaining availabilities in other demands. This second ordering is important for smaller demands, the search will choose workers that are less likely to be needed in other demands.

It also never considers the fictitious worker  $\sigma$  for the worker value as it is not even considered for most available worker.

This value heuristic will in practice find solutions much quicker than a traditional *min* value heuristic.

# Chapter 5

## Implementation (TODO title)

In this chapter, we describe our implementation for the models presented in Chapter 4. The implementation is done in Scala using *OscAR* (3.2.2) for the Constraint Programming model and *Gurobi Optimizer* (3.1.1) for the Mixed Integer Programming model.
